# Introducing Today's Project!

## What is Amazon VPC?

Amazon VPC is a private network in AWS that lets you securely manage resources with custom IP ranges, route tables, and security settings. It's useful for isolating workloads and controlling traffic flow for better security.

## How I used Amazon VPC in this project

I used Amazon VPC to create a secure cloud network with subnets, route tables, a security group, and a network ACL to manage traffic flow and enhance security for resources inside the VPC.

## One thing I didn't expect in this project was...

I didn't expect custom network ACLs to block all traffic by default, requiring manual rules for allowing inbound and outbound traffic.

## This project took me...

This project took me around one hour to complete, including setting up the VPC, configuring security rules, and associating network ACLs with subnets.

# Route tables

Route tables are like a GPS for network traffic, defining rules for where data should go within a VPC. They ensure that resources in a subnet can communicate internally or with external networks.

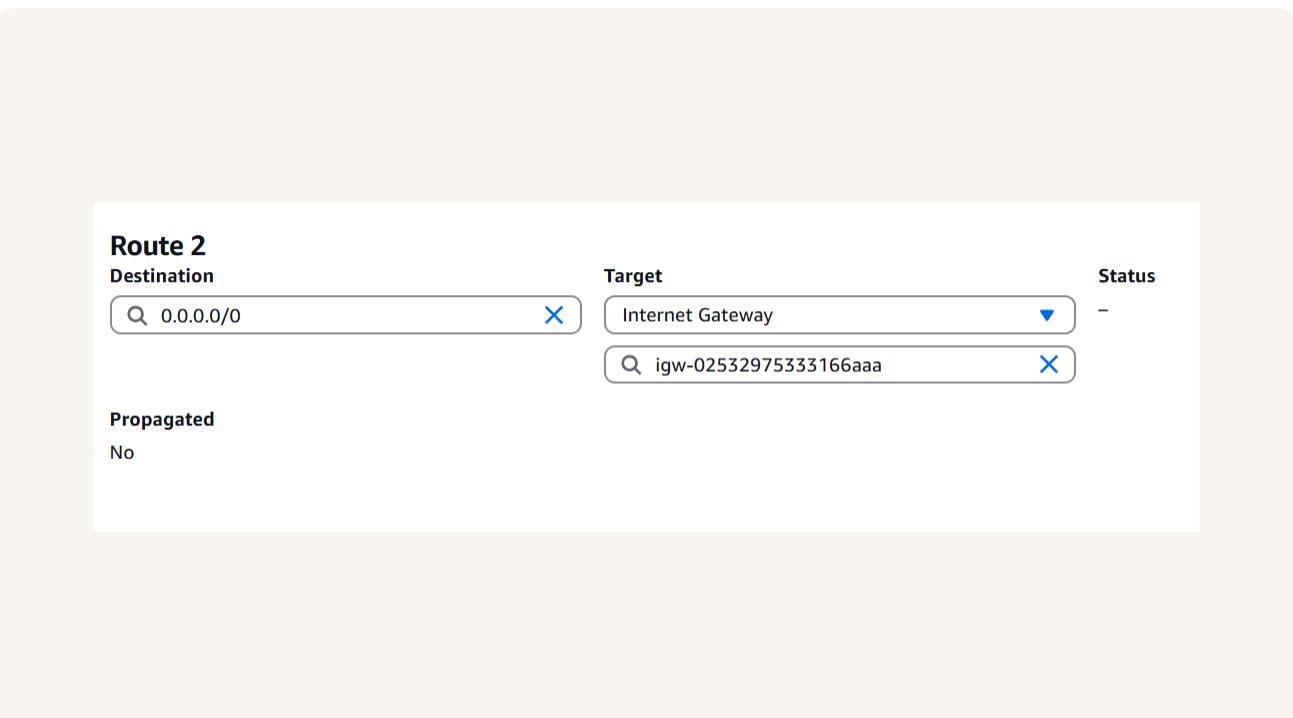

Route tables are needed to make a subnet public because they define how traffic leaves the VPC. A route directing 0.0.0.0/0 to an internet gateway allows instances to access the internet.

Route 2		
Destination	Target	Status
<input type="text" value="0.0.0.0/0"/> <span>X</span>	<input type="text" value="Internet Gateway"/> <span>▼</span>	-
	<input type="text" value="igw-02532975333166aaa"/> <span>X</span>	
Propagated		
No		

# Route destination and target

Routes are defined by their destination and target, which mean the destination is the IP range traffic wants to reach, while the target is the path it takes (e.g., an internet gateway or local VPC).

The route in my route table that directed internet-bound traffic to my internet gateway had a destination of 0.0.0.0/0 and a target of NextWork IG (Internet Gateway).

# Security groups

Security groups are virtual firewalls that control inbound and outbound traffic to AWS resources. They define who can access a resource and how data flows, ensuring secure communication within a VPC.

## Inbound vs Outbound rules

Inbound rules are rules that control traffic entering a resource. I configured an inbound rule that allows HTTP traffic (port 80) from anywhere (0.0.0.0/0), making my resources publicly accessible.

Outbound rules are rules that control traffic leaving a resource. By default, my security group's outbound rule allows all outbound traffic, meaning resources can send data anywhere on the internet.

# Network ACLs

Network ACLs are subnet-level firewalls that control inbound and outbound traffic using stateless rules. They check data packets at the subnet boundary, allowing or denying traffic based on predefined rules.

## Security groups vs. network ACLs

The difference between a security group and a network ACL is that security groups apply to individual resources, while network ACLs apply to entire subnets, requiring explicit rules for both inbound and outbound traffic.

# Default vs Custom Network ACLs

**Similar to security groups, network ACLs use inbound and outbound rules**

By default, a network ACL's inbound and outbound rules will allow all traffic, meaning any data packet can enter and leave the subnet unless modified by custom rules.

In contrast, a custom ACL's inbound and outbound rules are automatically set to deny all traffic until specific allow rules are manually added, ensuring no unauthorized access by default.
